

# **Pytorch and Titanic: Connecting the Math to Coding**

Now that you've seen the very basics of how to use <code>pytorch</code>, we're going to see how to apply it to a machine learning problem. Along the way we'll make connections back to the Titanic dataset and help solidify your understanding of the connection between the math we've been learning and the code we'll be writing using <code>pytorch</code>.

To get started, let's load our trusty Titanic dataset.

#### In [0]:

In the Assignment 6 companion notebook we fit two models:

- 1. We used the Age and Sex columns along with a synthetic feature called is young male as inputs to a logistic regression model in order to predict whether someone survived.
- 2. We used just the Age and Sex as inputs to a multilayer perceptron model in order to predict whether someone survived.

In this notebook we'll be implementing both of these models in pytorch. To get started, let's perform the following data processing / cleaning steps.

- 1. Get rid of any passengers where we don't know their age (don't do this in a real machine learning application as it will skew your results).
- 2. Convert the Sex column to a dummy variable called male that will take on value 1 if the passenger is male and 0 otherwise.
- 3. Create the is young male column that will be 1 for males under the age of 5 and 0 for everyone else.

#### In [0]:

```
# get rid of null values for age since this is just an illustrative example.
# this would not be a good thing to do if we were trying to evalutate the
# performance of a model.
df_filtered = df[['Age', 'Sex', 'Survived']].dropna()
is_young_male = ((df_filtered['Sex'] == 'male') & (df_filtered['Age'] < 5)).astype(int)
is_young_male.name = 'is_young_male'
experiment_1_data = pd.concat((pd.get_dummies(df_filtered['Sex'], drop_first=True),
df_filtered['Age'], is_young_male), axis=1)
experiment_1_outputs = df_filtered['Survived']
experiment_1_data</pre>
```

Next, we'll go ahead and build our logistic regression model just as we did in the assignment 6 companion notebook. The only small twist we will introduce is turning off the ridge term of the model so that it will make comparing the results from this analysis to what we do in pytorch easier.

```
In [0]:
```

```
from sklearn.linear_model import LogisticRegression

model = LogisticRegression(solver='lbfgs', penalty='none') # setting solve silences annoying
warning
model.fit(experiment_1_data, experiment_1_outputs)
print("coefs", model.coef_)
print("intercept", model.intercept_)

coefs [[-2.67342472  0.00808732  2.38307187]]
intercept [0.9018627]
```

### **Notebook Exercise 1 (10 minutes)**

This is a bit of review. Provide an interpretation for the coefficients learned by the logistic regression model (e.g., what do they mean for the prediction of whether a passenger would survive).

# **Reimplementation in Pytorch**

Next, we'll be using pytorch to implement our own version of logistic regression! When creating a neural network model (remember, we can think of logistic regression as a perceptron with 2 layers, an input and an output), you create a class that inherits from nn.Module. We'll give you an implementation of logistic regression and then give a detailed breakdown of the key lines.

```
In [0]:
```

```
from torch import nn
import torch
from torch.autograd import Variable

class LogisticRegressionPytorch(nn.Module):
    def __init__(self):
        super(LogisticRegressionPytorch, self).__init__()
        self.linear = nn.Linear(3,1)

def forward(self, X):
        """ Propagate data through the network.

        This model first applies the linear layer and then a sigmoid
        """
        X = self.linear(X)
        return torch.sigmoid(X)
```

Here is a breakdown of some of the key lines in this implementation.

Inherit from the super class nn.Module:

```
class LogisticRegressionPytorch(nn.Module):
```

Since we're inheriting from nn.Module, we need to make sure to call the \_\_init\_\_ method of nn.Module when initializating our class.

```
super(LogisticRegressionPytorch, self).__init__()
```

The linear layer will store the weight vector of our model. The \$3\$ arises from the fact that our model will have 3 inputs (age, male, and is young male). It is very important that you store your layers as attributes of your class. This is how pytorch knows about them and can optimize them. If you need to have a list of layers, look into nn.ModuleList.

```
self.linear = nn.Linear(3,1)
```

The forward function is the heart of the model. It runs input data through the network and returns the output. Writing such functions usually amounts to passing data between the various layers that were created in the \_\_init\_\_ method. The syntax for this is a little funny. For instance, in the code below, self.linear(X) implicitly calls the forward function of the nn.Linear class. Yes, we find this kind of weird, but that's how it's done in pytorch. Thius is really just a syntactic quirk rather than anything substantive that you need to worry about. The last step of the function involves applying the sigmoid and returning the result.

Next, we'll show how to pass some data into the model.

```
def forward(self, X):
```

```
""" Propagate data through the network.

This model first applies the linear layer and then a sigmoid

"""

X = self.linear(X)

return torch.sigmoid(X)
```

#### In [0]:

```
# sample_data represents a male passenger who is 10 years old
sample_data = Variable(torch.FloatTensor([1.0, 10.0, 0.0]))
model_pytorch = LogisticRegressionPytorch()
model_pytorch(sample_data)
```

#### Out[0]:

```
tensor([0.0237], grad fn=<SigmoidBackward>)
```

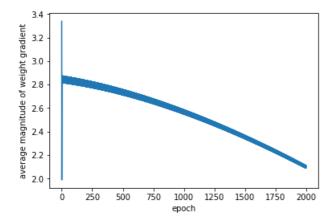

The code we computed the probability that the specific passenger would survive. It is very important to realize that right now the model *has not been trained*. This means that we don't expect the output of the model to make any sense (although it might just by chance). If you rerun the code repeatedly, you'll get different results due to the fact that the weights are initialized randomly.

Next, we're going to actually train the network! This is where things get interesting. We'll have you run the code and then point out a couple of key components.

#### In [0]:

```
model pytorch = LogisticRegressionPytorch()
model_pytorch.train()
optimizer = torch.optim.SGD(model_pytorch.parameters(), lr=0.01)
criterion = torch.nn.BCELoss()
grad_magnitudes = []
X_data = Variable(torch.Tensor(np.array(experiment_1_data)))
y_data = Variable(torch.Tensor(np.array(experiment_1_outputs)))
for epoch in range(2000):
   optimizer.zero_grad()
    # Forward pass
   y_pred = model_pytorch(X_data)
    # Compute Loss
    loss = criterion(y_pred, y_data)
    # Backward pass
    loss.backward()
    for name, param in model_pytorch.named_parameters():
        if name == 'linear.weight':
            grad_magnitudes.append(np.abs(param.grad.numpy()).mean())
    if epoch % 1000 == 0:
        print("epoch", epoch)
        for name, param in model pytorch.named parameters():
            print(name, "value", param.data, "gradient", param.grad)
    optimizer.step()
import matplotlib.pyplot as plt
%matplotlib inline
plt.plot(grad magnitudes)
plt.xlabel('epoch')
plt.ylabel('average magnitude of weight gradient')
plt.show()
/usr/local/lib/python3.6/dist-packages/torch/nn/modules/loss.py:512: UserWarning: Using a target s
ize (torch.Size([714])) that is different to the input size (torch.Size([714, 1])) is deprecated.
Please ensure they have the same size.
 return F.binary_cross_entropy(input, target, weight=self.weight, reduction=self.reduction)
epoch 0
linear.weight value tensor([[-0.5514, -0.0720, 0.0020]]) gradient tensor([[-0.0882, -9.9144, -0.0
linear.bias value tensor([-0.2926]) gradient tensor([-0.3188])
epoch 1000
linear.weight value tensor([[-1.2754, -0.0347, 0.1262]]) gradient tensor([[-0.0685, -7.5624, -0.0
```

137]])
linear.bias value tensor([0.0040]) gradient tensor([-0.2397])

Put the model into training mode (this only affects certain models that behave differently during training and testing). Even though it doesn't affect our logistic regression model, calling the .train function is a good habit to get into.

```
model_pytorch.train()
```

Create an optimizer that will tune the parameters of the network. Here we are using an algorithm called *stochastic gradient descent*. It's a very popular choice for an optimizer. Similarly to gradient descent it optimizes a function by stepping down the gradient (step size is given by learning rate or <code>lr</code>). Where it differs from normal gradient descent is that it doesn't necessarily use all of the data to compute the gradient. If you have a big dataset, it might only use a small number of data points, compute gradient over those, and then step down that estimate of the gradient. The collection of datapoints used for estimating the gradient is called a *mini batch*. In this example we are using the entire dataset each time, so we are really doing normal gradient descent.

```
optimizer = torch.optim.SGD(model_pytorch.parameters(), lr=0.01)
```

The criterion defines the loss function we are minimizing. When the training outputs are binary, the BCELoss function is equivalent to the log loss that we have been using in this course.

```
criterion = torch.nn.BCELoss()
```

In order to operate on data in pytorch, you have to convert any matrix or vector data into a pytorch variable. This should be familiar based on the tutorial you went through earlier.

```
X_data = Variable(torch.Tensor(np.array(experiment_1_data)))
y_data = Variable(torch.Tensor(np.array(experiment_1_outputs)))
```

An *epoch* in neural network training is a single pass through the data. In this case we are taking a single gradient step on the whole dataset, so the number of epochs is the same as the number of gradient steps.

```
for epoch in range(200):
```

This tells the optimizer to throw away any gradients it has accumulated from previous data (do not forget to call this!!!).

```
optimizer.zero_grad()
```

Apply the forward model to get predictions.

```
y_pred = model_pytorch(X_data)
```

Calculate the loss of the model by comparing its predictions with the actual outputs.

```
loss = criterion(y_pred, y_data)
```

Use backpropagation to compute the gradient of all of the model parameters with respect to the loss.

```
loss.backward()
```

Calculate the gradient magnitudes so we can make a plot after training.

```
for name, param in model_pytorch.named_parameters():
    if name == 'linear.weight':
        grad_magnitudes.append(np.abs(param.grad.numpy()).mean())
```

Print out the values of the parameters and the gradient of the parameters with respect to the loss every 50 epochs.

```
if epoch % 50 == 0:
    print("epoch", epoch)
    for name, param in model_pytorch.named_parameters():
        print(name, "value", param.data, "gradient", param.grad)
```

Perform the gradient step.

```
optimizer.step()
```

# Notebook Exercise 2 (30 minutes)

- (a) Explain the output you see when you run the previous code cell. How are the weights changing over time? How is the gradient changing over time? Is the algorithm close to converging (i.e., computing the optimal solution)? How would you know if it has converged?
- (b) Increase the number of epochs until you get convergence. How many did it take?
- (c) Tune the learning rate to some other values. How does this change the algorithm's behavior?
- (d) Change the optimizer to the ADAM optimizer by swapping out the previous optimizer with this new line of code.

```
optimizer = torch.optim.Adam(model_pytorch.parameters())
```

Roughly many epochs does it take to reach convergence now?

# **Multilayer Perceptron**

Now that we've shown you how to implement the logistic regression model, we want you to implement the MLP model from the previous companion notebook. Remember, the MLP had 2 input features (we didn't use is young male as an input) and 2 hidden units. We'll provide you with the skeleton of the code as well as some code to generate the visualization from the previous notebook.

```
In [0]:
```

```
# start from this and modify it
class LogisticRegressionPytorch(nn.Module):
    def __init__(self):
        super(LogisticRegressionPytorch, self).__init__()
        self.linear = nn.Linear(3,1)

def forward(self, X):
    """ Propagate data through the network.

    This model first applies the linear layer and then a sigmoid
    """
    X = self.linear(X)
    return torch.sigmoid(X)
```

# Notebook Exercise 3 (20 minutes + 20 minutes of optional work)

Non-optional: modify the code above regression class to create a class called TitanicMLP that has 2 input units and 2 hidden units. Train your network on the Titanic dataset. We have defined a function called visualize\_model\_probs for visualizing the probability plot that we saw in the last companion notebook (this code should be run after the model is done training).

Optional: visualize the hidden unit representations in the network (similar to what we did in the companion notebook last time).

```
In [0]:
```

```
def visualize_model_probs(model):
    xx, yy = np.mgrid[-.1:1.1:.01, 0:85:.1]
    grid = np.c_[xx.ravel(), yy.ravel()]
    probs = model(Variable(torch.Tensor(grid))).detach().numpy().reshape(xx.shape)

    f, ax = plt.subplots(figsize=(8, 6))
    contour = ax_contourf(xy__vy__probs__25__cman="pdpy"
```

#### In [0]:

```
class TitanicMLP(nn.Module):
    def init (self):
        super(TitanicMLP, self).__init__()
